Recent Reactor-Based Measurements of Theta13

Tuesday, 14 May 2013 14:00 (20 minutes)

Several recent experiments have measured a significant deficit in electron antineutrinos at distances of 1-2 km from nuclear reactors. In the 3-neutrino framework, this deficit is attributed to a nonzero mixing angle θ_{13} . Three ongoing experiments, Double Chooz, RENO, and Daya Bay, continue to improve their experimental precision. I will compare these experiments, focusing on common techniques for neutrino detection, challenges in making the measurement, and recent results.
