Results from MINOS and the status of MINOS+

Monday, 13 May 2013 14:00 (25 minutes)

MINOS is a long-baseline accelerator neutrino oscillation experiment that is designed to precisely measure the neutrino mixing parameters that are associated with the atmospheric mass-squared splitting. MINOS has currently completed data taking in its nominal beam configuration, and the results from that final data sample will be presented. In addition, MINOS will transition to the MINOS+ experiment and will begin taking data in a higher energy beam configuration that will allow the experiment to probe phenomena that is not accessible in the lower energy mode. The future plans of the MINOS+ experiment will be presented.
